Real estimates of mortality following COVID-19 infection

As of March 1, 2020, 79,968 patients in China and 7169 outside of China had tested positive for coronavirus disease 2019 (COVID-19). Among Chinese patients, 2873 deaths had occurred, equivalent to a mortality rate of 3.6% (95% CI 3.5–3.7), while 104 deaths from COVID-19 had been reported outside of China (1.5% [1.2–1.7]). However, these mortality rate estimates are based on the number of deaths relative to the number of confirmed cases of infection, which is not representative of the actual death rate; patients who die on any given day were infected much earlier, and thus the denominator remains unknown.

The maximum incubation period is assumed to be up to 14 days, whereas the median time from onset of symptoms to intensive care unit (ICU) admission is around 10 days. Recently, WHO reported that the time between symptom onset and death ranged from about 2 weeks to 8 weeks. We re-estimated mortality rates by dividing the number of deaths on a given day by the number of patients with confirmed COVID-19 infection 14 days before. On this basis, using WHO data on the cumulative number of deaths to March 1, 2020, mortality rates would be 5.6% (95% CI 5.4–5.8) for China and 15.2% (12.5–17.9) outside of China. Global mortality rates over time using a 14-day delay estimate are shown in the figure, with a curve that levels off to a rate of 5.7% (5.5–5.9), converging with the current WHO estimates. Estimates will increase if a longer delay adjusted estimation indicates that mortality rate of COVID-19 could be as high as 20% in Wuhan, the epicentre of the outbreak. These findings show that the current figures might underestimate the potential threat of COVID-19 in symptomatic patients.

The maximum incubation period is assumed to be up to 14 days, whereas the median time from onset of symptoms to intensive care unit (ICU) admission is around 10 days.
